

Non-asymptotic confidence bands on the probability an individual benefits from treatment

Gabriel Ruiz, Oscar Madrid-Padilla, Department of Statistics, UCLA

Introduction

Figure 1: Hypothetical distribution.

In [1], we seek **closed-form**, non-asymptotic confidence bands on the **inestimable** probability an individual benefits from treatment (**PIBT**):

1. $\Pr(Y_i(1) - Y_i(0) > \delta)$
2. $\Pr(Y_i(1)/Y_i(0) > \delta)$ (positive outcomes)
3. $\Pr(Y_i(1) - Y_i(0) > \delta | X_i = x)$.

Insight 1: Practical Interpretation

With $(1 - \beta) \times 100\%$ confidence, PIBT is contained between
 [Estimator for lower bound on PIBT]
 – [Margin of error for PIBT bounds]
 and
 [Estimator for upper bound on PIBT]
 + [Margin of error for PIBT bounds].

Insight 2: Power Analysis For RCT

- Margin of error for PIBT bounds = $\left(\frac{\log(4/\alpha)}{2}\right)^{\frac{1}{2}} \left(n_0^{-\frac{1}{2}} + n_1^{-\frac{1}{2}}\right)$ with $(1 - \alpha) \times 100\%$ confidence.

Figure 2: Power analysis based on our *Theorem 1* in [1].

Insight 3: Heterogeneity in PIBT

- Key: use residuals

$$Y_i(w) - \hat{\mu}_w(X_i).$$

- Confidence Level Correction:

$$1 - \alpha - \Pr\left(\bigvee_{w=0,1} \sup_x |\hat{\mu}_w(x) - \mu_w(x)| > t_w\right).$$

- Simultaneous inference at all strata x .

At sample size n , what is the uniform Margin of Error on efficacy bounds at the 90% confidence level?

Figure 3: Power analysis based on our *Theorem 3* in [1] applied to canonical linear model.

Methodology

- Extension of existing **plug-in estimation** framework [2].
- **Distribution-free** bounds on CDF of difference [3] (any possible dependence).
- Non-parametric Empirical CDF deviation inequality [4].
- Neyman-Rubin causal model; marginal and conditional ignorability.
